N/A N/A Advanced Reading Overview Advanced Reading Advanced Reading ** The Controlled Substances Act (CSA) programming information displayed applies to substances regulated by federal law. There may be variations in CSA schedules between individual states. Always consult your health care provider to make sure that the information on this page applies to your personal circumstances. Medical Disclaimer ADHD Treatment Attention Deficit Hyperactivity Disorder (ADHD) is a condition that occurs in childhood and adolescence, although it can last into adulthood, and even be initially diagnosed in adulthood. ADHD and Attention Deficit Disorder (ADD) used to be considered separate conditions. Now, the term ADHD includes ADD. Symptoms of ADHD include: hyperactivity and impulsive behavior to maintain attention or be carefully distracted by external stimuli combination of impulsive behavior and inattentionPsychotherapy, behavioral training, and education can be effective for many people with ADHD. However, ADHD treatment often includes medications. Before resorting to these drugs, the FDA has issued a boxed warning stating that amphetamine misuse can cause sudden death and serious cardiovascular adverse reactions. Providers who prescribe medications for this class of medicines can detect possible heart problems. In some cases, depending on your provider, your provider may get a basal electrocardiogram before starting a stimulant medication. Drug manufacturers also list contraindications that include: Advanced arteriosclerosis, symptomatic cardiovascular disease, moderate to severe hypertension, hyperthyroidism, known hypersensitivity or idiosyncrasies to sympathomimetic amines, glaucoma, and agitated states. Dextroamphetamine and amphetamine (brand name: Adderall) and dextroamphetamine (brand name: Dexedrine) are central nervous system stimulants. They are approved for the treatment of ADHD and also for narcolepsy (a neurological condition marked by severe daytime sleepiness). These medications are more stimulating than methylphenidate (brand name: Ritalin), which is often the first medicine your doctor could give you. However, variations in individual experiences with each drug have been reported. Why it is prescribed and used correctly, both medications can help people with ADHD focus more effectively. Because they contain amphetamines, both drugs are sometimes abused. Over time, tolerance can develop, as it may depend, and both substances have been reported to have a high potential for abuse. Abuse. the actual mechanism of action for both drugs is unknown, it is believed that the drug works in two ways. It is believed that the drug causes neurotransmitters to last longer in the parts of the brain that control attention and alertness, and it is also believed to increase the concentration of neurotransmitters. Neurotransmitters are chemicals that send signals from one brain cell to another. By making these areas more active, medications can help a person focus their attention. Surprisingly, stimulants can help calm a person with ADHD. Forms and dosageDextroamphetamine and amphetamine (Adderall) and dextroamphetamine (Dexedrine) are usually taken in tablet form once daily. However, they can also be taken twice (or even three times) a day, depending on how a person responds to the medicine. Both drugs are FDA approved to treat ADHD in adults and children 3 years and older. If your doctor prescribes dextroamphetamine, the starting dose will often be between 2.5 mg and 5 mg per day. You may need to adjust the dose gradually, as your doctor monitors how well the medicine is working. Adult doses range from 5 mg to 60 mg per day. Children may be given doses ranging from 2.5 mg to 40 mg per day. There are several strengths and an extended form of release, so the dosage can be individualized. Dextroamphetamine and amphetamine also start at a low dose, usually 5 mg and can be gradually adjusted by your doctor. The maximum daily dose is 40 mg to 60 mg per day. Children often start at 2.5 mg a day, and gradually increase to a maximum of 40 mg per day. There are several strengths and also an extended release form, which makes it easier for your doctor to find the right dosage for you. You will need a written prescription from your doctor to get any of the medicines. CostBoth drugs are available in generic forms, which are less expensive than brand-name drugs. Ask your doctor and talk to your pharmacist about taking the generic form. The possible side effects of both drugs are similar. Both can increase blood pressure. The increase is usually minor, but if you've been diagnosed with a heart condition or hypertension, talk to your doctor about the risks and benefits of these medications. The two medications can also cause: diarrhea or symptoms of streatorinary such as burning while urinating laryngpalpitations or irregular loss of mouth heartbeats of reduced appetite weight growth (in children)insomniachange in libido and impotenceIn rare cases, dextroamphetamine and amphetamine (Adderall) use can result in alopecia, which is hair loss scalp and other parts of the body. People taking any of the medicines should take the lowest dose possible, in order to avoid a possible overdose. Although rare, both medications can cause peripheral vasculopathy, which is a problem with blood vessels in your fingers, hands, legs, and feet. If your fingers begin to feel numb or cold, or if it wounds appear on your fingers or fingers if you have a psychiatric illness or seizure disorder, these medications can make your symptoms worse. Tell your doctor about your medical history before taking a stimulant medication. Dextroamphetamine and amphetamine (Adderall) can cause motor tics or speech changes similar to Tourette's syndrome. Changing the dose or switching to a different medication can alleviate some of these problems. Both drugs have a high potential for abuse, and prolonged use of these drugs have been associated with psychological dependence. These medications may not be appropriate to take if you have a history of substance abuse, and some prescribers will not write

prescriptions for people who have had a history of addictive disorders. Keep both medicines in a safe place in your home. Pregnancy and lactation Extensive studies have not been conducted on how any of the medicines affect pregnant women and their babies. However, there are concerns that amphetamines, even used at prescribed levels, may pose risks to a developing fetus, such as lower birth weight or premature birth. There is also a risk of behavioral problems in childhood. Nursing mothers should not take these medicines. Amphetamines can pass through breast milk and have toxic effects on babies. Drug holidays If you take a stimulant medication, you may experience side effects that may include loss of appetite and weight loss. Children may also experience reduced growth. Your doctor may prescribe a medication vacation, which is a deliberate interruption of treatment for a specific amount of time and purpose, such as identifying side effects. For example, your doctor may prescribe a medication vacation for your child during the summer when the school is not in session. Everyone taking stimulant drugs should be periodically reassessed to see if the drug remains effective and necessary. Possible drug-amphetamine interactions in both medications may interact negatively with several other medications. These medications may interfere with the action of anti-seizure medications, such as ethosuximide, phenobarbital, or phenytoin. Medications can block the sedative effects of antihistamines on allergy medications. Antihypertensive medications may be less effective at lowering blood pressure if you take any of the medications. There is also a risk of complications if you take these ADHD medications and certain antidepressant medications or If you take any of these stimulant medications with multivitamins, iron, or fluoride, drug levels may decrease and may not work as well. If you take antacids, certain antibiotics, MAO inhibitors, or proton pump inhibitors with any of the medications, the level of the drug may increase. If you're prescribed any of the medicines, be sure to tell your doctor and pharmacist about all other over-the-counter medications and products you're currently taking. Ask your health care providers about and side effects. The efficacy and safety profiles of both drugs are relatively similar. However, because each person responds differently to medications, your care may be better with one medication compared to the other. Your doctor may try one medicine and then the other to determine which one is most effective. You may also have side effects with one medicine you don't have with the other. You should know within several days of starting a new drug if it is effective and how well it tolerates side effects. Dextroamphetamine and amphetamine (Adderall) is more widely prescribed than dextroamphetamine (Dexedrine), but that doesn't mean it wouldn't do as well or better in dextroamphetamine. Make sure your doctor has your full medical history so they can make an informed recommendation. Don't hesitate to order a different medication or a different dose, if you're not experiencing adequate symptom relief with the first one you try. Treat.
