Round ligament of liver and falciform ligament

This article contains a list of references, related readings, or external links, but the sources remain ambiguous because they lack line-by-line citations. Please help to improve this article by offering more precise excerpts. (June 2015) (Learn how and when to remove this template message)

Falciform ligamentFalciform ligament is seen here, dividing the liver from the front into a left and right lobe. Liver viewed from above. Falciform ligament liverDetailsIdentifiersLatinligamentum falciforme hepatisTA98A10.1.02.303TA23771FMA15823Anatomic terminology[edit on Wikidata]

Falciform ligament in the right lateral lobes can be seen separating the left medial falciform ligament to the front body wall, and separates the liver into the left medial lobe and the right lateral lobe. Falciform ligament, Latin for 'sickle-shaped', is a peritoneum wide and thin fold, its base is directed down and back and up and forward at the top. Falciform ligament sagging down the hilum of the liver. The structure falciform ligament extends tilted back from the front part of the abdomen, with a surface that comes into contact with peritoneal behind the right rectus abdominis muscle and diaphragm, and other contact with the liversol lobe. Ligament right rectus abdominis extends to the back surface of the muscle sheath from the lower part of the diaphragm, as low as the belly; With its right margin, it extends back to the back surface up the notch on the front margin of the liver. It consists of two layers of peritoneum that are closely combined together. Its base or free edge contains round bonding and paraumbilical vessels between its layers. Development This is an embryonic ventral mesenteric residue. The belly vein of the fetus causes round ligament of the adult liver, located at the free limit of falciform ligament. Clinical significance Falciform ligament can be channeled if an individual suffers from portal hypertension. Due to increased venous obstruction, blood is pushed from the liver to the front abdominal wall, where if there is a blood deposit, it causes the veins around the belly to dil expand. These veins spread out of the belly, they can give the appearance of a head (belly) with snake (veins) hair - this caput is called medusae. [1] Additional images showing primitive mesentery in a six-week-old human embryo Section. Section showing peritoneum curves in your upper wife. A cadaver liver seen from above, showing falciform ligament at the top. The round ligament divides the liver part into the medial and lateral sections. [1] [2] Since the round ligament is an embryonic belly venink, it is found only in placental mammals. After the child is born, the belly ven fibrous tissue, round ligament degeneration. [3] In adulthood, small parabllical vens remain at the resex of the bond. These serious portal hypertension act as a portacaval anastomosis, resulting in a caput medusae. [4] [5] The umbilical cord/round ligament is located around the belly and is an important symbol of the inner surface of the front abdominal wall. [1] Additional Images of liver round ligament.
