Above the best hvac

The men and women who keep you cool and warm in winter are called heating, ventilation and air conditioning technicians. HVAC technicians install and repair residential and commercial heating and cooling equipment. Some HVAC technicians work in construction, but most do installation and repair work for local HVAC companies as employees or independent contractors. The Bureau of Labor Statistics reports that the number of HVAC technician jobs is expected to grow by a 34 percent between 2010 and 2020. Photo: hvacwoodbridge.org If you are considering a new system for your home, talk to your architect or designer first. Conversations with HVAC contractors are likely to follow, although you or your designer may also want to consult a specialist – a heating technician – in case your construction project imposes unusual requirements. Talk in detail about your needs. If your budget is tight, you need to identify critical data. If you can afford to think wider, consider the extra comfort of, for example, radiant underfloor heating. If you are not satisfied with your current system or want to add wetting or a filtration system, get bids for these costs. In most cases, expanding your existing system or adding a smaller heater is the cheapest option. Here are a few other considerations: The air conditioning option. As a rule of thumb, if local temperatures rarely exceed 85 degrees Celsius, you probably don't need central air conditioning. On the other hand, central air is often considered by brokers as a valuable selling point, so if there is a chance you will be transferred to another region or are likely to put your home on the market for whatever reason in the near future, central air conditioning can be a good investment. Top-of-the-market houses get top-of-the-market prices because they have all the bells and whistles. For people with asthma and other allergy problems, central air with its ability to filter and condition household air can also have health benefits. Beware of oversized systems. Strange though it sounds, too much heating capacity will make a system less efficient. It will ensure that the system can be cycled on and off regularly, causing excess wear on the components. The system may never reach peak temperatures. To be sure that your system is suitable for your home, ask your HVAC contractor, heating engineer, or who the system designed to run you through the calculation. The process consists of determining what the heating load is (based on an arithmetic formula that factors in the size of your home, the insulation, and the local climate). The system capacity must not be 25% greater than the calculated heating load. Simple is usually less expensive. Staying with your existing system is almost certainly the cheapest route. If your system's capacity it can be extended to heat (or cool) new spaces, that approach will probably be less expensive than installing an entirely new system. Buy quality. Good shoppers don't always buy bargains. Buying durable boilers or ovens that come with long warranties often costs more initially, but over the years, presents fewer headaches. Good ovens are often guaranteed for twenty years, boilers for thirty, heat pumps for less. Think local. Don't buy equipment that no one in your area can maintain. If the only HVAC contractor who will offer your job is a long distance call away, you might ask for trouble. These advanced modern systems require occasional checks by service people who are familiar with their design, installation, and individual characteristics. An industry study found that half of all service calls were the result of incorrect or inadequate maintenance. In this course you start by identifying the different steps that an HVAC (Heating, Ventilation and Air Conditioning) engineer needs to follow in order to arrive at a good design while working with the architect. Next, you'll learn how to distribute heat and cold with air and water systems, what temperature levels you use both in both and how that compares to the type of energy supply and the thermal quality of the building construction. You will further deepen your knowledge about air treatment units and how to moisten and dehumidize air when needed and what that means for energy consumption. Because ventilation systems are often responsible for local thermal discomfort, you will also discover how different distribution systems lead to different comfort experiences and different indoor air qualities and know what simple control techniques can be applied. Finally, you will study a modern complex system consisting of an aquifer thermal storage, heat pump, boiler, solar collector, PV cells, air treatment unit, water and air distribution systems. This will allow you to develop skills to capture the complexity of such HVAC systems and to understand the basic rules of how to monitor them to get the best out of them and how to use data from the Building Energy Management System to help you in this task. This course is part of the PCP Buildings as Sustainable Energy Systems. In the other courses in this program you will learn how to design buildings with low energy demand, how to choose a low-carbon energy supply and how to determine whether this will lead to a comfortable indoor environment. The development of this course is supported by Climate-KIC. How air is processed in an air treatment unit and how it is distributed to provide thermal comfort. How to distribute heat and cold with air systems, and what the associated pressure losses are. How to distribute heat and cold using a water system or a mixed air/water system. Choose which temperature levels to choose in both types of systems, efficiency and thermal comfort. How to make complex combinations of (renewable) energy equipment manageable and controllable.
