Facts about the pacific northwest tree octopus

Help Save the ENDANGERED from EXTINCTION! A rare photo of an elusive tree octopus (Enhanced from a cropped telephoto) A Pacific Northwest tree octopus (*Octopus paxarbolis*) can be found in the moderate rainforests of the Olympic Peninsula on the west coast of North America. Their habitat is located on the East side of the Olympic mountains, adjacent to the Hood Canal. This solitary sefalopoda reaches an average size (measured from the tip of the arm to the tip of the coat,) 30-33 cm. Unlike most other cephalopods, amphibian tree octopuses, spend only their early life and the period of their mating season in their ancestral aquatic environment. Due to the humidity of the rainforest and special adaptations of the skin, they can keep it from drying for a long period of time, but given the chance they prefer to rest in the stretched water. Intelligent and in curiosity (having the largest brain-to-body ratio for any mollusk), the tree octopus explores its arboreal world with touch and vision. Adaptations of its ancestors originally evolved in the three-dimensional environment of the sea have been well used in the spatially complex labyrinth of coniferous Olympic rainforests. The challenges and richness of this environment (and the intimate way in which it interacts with it,) can take into account the development of sophisticated tree octopus behavior. (Some evolutionary theorists think that arboreal adaptation is what lays the grounding in primates for the evolution of the human mind.) Reaching out with one of its eight arms, each covered in sensitive suckers, the tree octopus may take a branch to pull itself together in the form of a locomotion called tentaculation; or he may be prepared to attack insects or small vertebrates, such as frogs or rodents, or steal eggs from bird nests; or he might even be examining some of the objects that caught him poshly, instinctively wanting to manipulate them with his confit limbs (really deserveing the title of sensory organ more than just limbs,) to better figure it out. The map estimates the maximum range of octopus trees, including spawning water Octopus trees have vision comparable to humans. In addition to allowing them to see prey and their environment, it helps them in inter-octopus relationships. Although they are not social animals like us, they display each other their emotions through their ability to change the color of their skin: red shows anger, white fear, while they usually maintain a speckled brown tone to blend in with the background. The reproductive cycle of the tree octopus is still associated with its roots in the waters of Puget Sound from where it came from. Every year, in Spring, tree octopuses leave their homes in the Forest Olympics and migrated towards the coast and, finally, their spawning site on the Hood Canal. There, they gathered ((real social time in their lives,) and finding a partner. After the male stores his sperm, he returns to the forest, leaving the female to find a nest of water in which to attach her strands from the egg cluster. The female will look after and care for her eggs until they hatch, refuse even to eat, and usually die of selfless. Young people will spend the first month or so floating through the Hood Canal, Admiralty Inlet, and as far north as North Puget Sound before eventually moving out of the water and starting their adult lives. Route 101, separating the Olympic Peninsula rainforest from the Hood Canal Although the tree octopus is not officially listed on the Endangered Species List, we feel that it should be added because the number is at a very low level for its breeding needs. The reasons for this dire situation include: decimal habitats with suburban logging and encroachment; road buildings that cut off access to water needed for spawning; predation by foreign species such as house cats; and its booming natural predator population, including bald eagles and sasquatch. What little has made it to the Channel is increasingly hampered in their reproduction by the growing pollution problem of agricultural and residential run-offs. Unless immediate action is taken to protect this species and its habitat, the Octopus tree of the Pacific Northwest will become just a memory. The possible extinction of the Pacific Northwest tree octopus is not an unwarranted fear. Other species of tree octopus—including douglas octopus and red ring madrona sucker—were once abundant throughout the Cascadia region, but have since become extinct due to threats similar to those faced by paxarbolis, as well as overharvesting by the now illegal tree octopus trade. Octopus Tree Hat from 1923 The history of the octopus tree trade is a sad one. Their voracious appetite for bird feathers has exhausted all decent species of the family, the fashionistas moved to cephalopodic accoutrements during the early 20th Century. Tree octopuses have become prized by the fashion industry as decorative decorations for hats, leading greedy trappers to wipe out entire populations to feed the swagger of the fashionable rich. Although fortunately this practice has been banned, its effects still reverberate today as the seizure of this millinery brings the number of tree octopuses below a tipping point where even minor environmental changes can lead to disaster. While efforts have been made in the past to preserve the remaining tree octopus habitat, this has been met with resistance by the timber industry, which has traditionally viewed tree octopuses as a nuisance, both because octopuses support valuable trees and are shrouded in moss from old growth forests — pitting conservation needs against the source of the timber — and because octopuses hide among felled trees often barrels of porridge stained with their ink. Exhibitions of traveling performances, such as this one by Glen Bones Hartzell from 1942, demonstrate the octopus tree to the masses who do not know (Click to enlarge) This disturbance caused many lumberjacks to regard the tree octopus as bad luck, resulting in the futile killing of octopuses while viewing the logging camp in a perverse attempt at eradicating the troublesome species. Anti-octopus sentiment is so strong among loggers that some even begin to fear that octopuses are vulnerable to attacking humans. This fear was sparked not least by gratuity stories involving tree octopuses harassing loggers and pathetic girls in Northwestern-themed pulp magazines of the 1930s-40s and various nipping, snarling, or meat-sucking heroes of the men's action magazines of the 1950s-60s. (Magazine publishers rely on cheap paper made from pulp and are happy to contribute to the wood industry's anti-octopus propaganda campaign.) To this day, the misunderstandings and fears of these gentle creatures can still be found among many old timers, although educational campaigns — and special octopus separators mounted on chainsaws — have largely stopped the practice of eradicating tree octopuses. The author of this article and its subsection is Lyle Zapato. This site is not associated with any school or educational organization, other than the Kelvinic University branch of the Wild Haggis Conservation Society.
