## Computer in accounting

You Stoval Productivity can be thwarted if your existing e-mail address is not configured correctly for your new computer. Depending on the email app you're using, you can easily update and receive emails that you missed between installs. Email apps like Microsoft Outlook and Mozilla Thunderbird transmit email accounts in a universal way. You can also create a new e-mail account on your new computer based on your existing email account information. Download and install the email app you used on your previous computer. If you are satisfied with the old e-mail application, install it using the installation disk that you originally used with the other computer. You can also try new email apps and still transfer your existing email account. Open File or Devices within the email app, and then click add a new email account. Enter the name you want to appear when recipients receive the email. Enter the user name and password to access your existing e-mail account, and specify incoming and outgoing e-mail servers if necessary. Some email applications automatically configure your email account. Other e-mail accounts must be created manually. Contact your e-mail provider to find out what the incoming and outgoing e-mail servers are. Save your changes and send yourself a test email. Sending a test e-mail ensures that you can successfully receive and send e-mail. Depending on the software, you will receive any emails that have not been verified or emails that have never been sent to your newly transferred email address. Be prepared to delete older emails as they come through. Open the e-mail software on your old computer, locate File or Tools, and then select Export. Depending on the software, you will be able to export the entire account, address book, or both. Click a location to save the exported file. Save the file to a CD or email it to yourself to download or transfer the data to your new computer. Open the new email app on the new computer. Look for Import. A window opens that allows you to search for the file you want to import. Locate the file that was saved to the CD or sent by e-mail. The new email automatically records and configures the account with the new settings and contacts. Macs accounted for one in 10 personal computers in the past two months, according to the latest analytics vendor data. Based on The California-based Net Applications tally, macOS - the operating system that runs only on Mac - 10% of global PC users in January and almost flat 9.9% in February. The latter figure was 3.7 percentage points higher than 12 months earlier, macOS is the personal computers. (Most of the one-year jump in macOS user share was credited to a one-time adjustment by Net Applications at the end of 2017; the move increased the total number of operating systems by 2.8 percentage points, or about three-quarters of the total increase, when the company deleted false traffic data published by criminals' bots.) Measurements from other metrics show that macOS - and, more broadly, Macs - were in even greater numbers. Irish company StatCounter, which, like Net Applications, tallies operating system shares by counting visitors to websites, claimed that macOS asparagus 12.4% of the world's PCs last month. This figure represents a much more modest increase - just seven-tenths of a percentage point - compared to the same month last year. As recently as two years ago, StatCounter estimates up macOS at just 9.4% of personal computers. Forming a tenth of all personal computers has long been a potential milestone for a Mac. That reaching the mark - after a 34-year pursuit of machines powered by Microsoft operating systems - is remarkable, said Bob O'Donnell, senior analyst at TECHnalysis Research. This is due to some level of growth driven by BYOD, said O'Donnell, referring to corporate policies covered by bring your own asset term. Over the years, companies have given employees a greater willingness to bring in their own assets. I assume it has something to do with [Mac growth]. O'Donnell also mentioned other likely reasons in part 10 of Mac's personal computer-based base, including a long-term trend from applications isolated by the operating system toward cloud-based applications, as well as security concerns. Macs are generally seen as safer as fewer attacks are directed at them, O'Donnell argued. The first of the two reasons, however, is likely to be more relevant than switching from apps-by-OS to cross-platform applications, as well as corporate BYOD, has contributed to a broader movement, O'Donnell pointed out. It's easier to add a non-Windows machine to an environment than it ever was, he said. True. Microsoft Windows, once the overwhelming powerhouse of technology tools, has been largely abandoned by consumers who have adopted more mobile solutions instead - primarily smartphones and tablets. Commercial customers remain the cornerstone of Windows in the operating system, but it's unclear whether corporate systems will be replaced at historical exchange rates or whether this market will shrink as well. The increase in Mac shares may have little or nothing to do with increased sales of Apple machines, as the increase in the user base has not been accompanied by a similar increase in timely sales and delivery. In 2017, for example, Apple said it had seded 19 million Macs, which Gartner says only PC shipments made up 7.2% during this period. This part of the shipments lower than the Mac portion of the personal computers used during the year. Instead of looking at sales and shipments, an increase in Mac sharing can keep owners on their systems longer than owners of Windows PCs. Or the latter's numbers simply put windows machines aside, actually knocking them off active reels while Mac owners continue to work on theirs. In both cases, a Mac, even if it didn't grow rapidly in raw numbers, would put together a higher percentage across. It's kind of ironic [that the Mac has reached a 10% milestone] when it's already fallen further into Windows machines than it ever was, claimed O'Donnell, ticking off everything for the better and wider i/o with the latter's larger range of screen sizes and resolutions. And in performance, Macs have lagged behind Windows-based personal computers, O'Donnell said. Copyright © 2018 IDG Communications, Inc. Several user accounts were once impractical on Windows, but they can no longer be used. If more than one person uses your computer, especially children or guests, you'll need to provide a separate user account for each person. This article focuses on windows-specific details, but the same common reasons apply to Mac OS X, Linux and even Android tablets with the new multi-user account feature. Why don't you use an account? If you're using a single user account on your PC, everyone will use the same app settings, files, and system permissions. App settings: If you use a single user account, users who use your computer will use the same browser. This allows others to use your online accounts, if you remain logged in, view your browser history, visit your bookmarks, etc. if you use multiple user accounts, everyone will have their own browser to sign in to without problems. The same is true for other applications, such as e-mail clients. Most programs use different settings for each user account. Files: If more than one person shares a user account, no one really has a private file. Anyone using the same user account can view the files. If you use multiple user accounts, other users will not be able to view files stored in the user folder in the C:\Users\Name folder. He won't be able to look at their files either. This provides additional privacy if other users are standard user accounts. Keep in mind that administrator users have full system permissions and can view all files on your computer. System permissions: Other user accounts can be standard or administrator accounts. If they're standard accounts, windows has built-in parental controls restrict your children's use of computers and view information about them. Anyone else who allows you to use your computer may have restricted permissions, so they cannot view files, install software, or modify the Computer. This can be especially useful if you want to close a computer so that less experienced users do not install malware. This is even more important in Windows 8, where you sign in by default with a Microsoft account, such as a Hotmail account. If you sign in with your Hotmail account, you'll still be signed in to the modern Mail app while you're using your PC. Anyone who uses their user account can open the Mail app, even if they're signed out of Hotmail or using Microsoft Outlook.com their browser. For multiple user accounts, you can even see when a user last logged on to the computer. Write how multiple accounts work When you create additional user accounts, you'll be able to sign in from the Windows sign-in screen. You can sign in to multiple user accounts at the same time— if you lock the screen and another user signs in, programs on the original desktop will continue to run while they use their own desktops. User accounts can be administrators or standard user accounts. Administrators have full access to the system, while standard user accounts have limited access, and require administrator permission to install software, change certain system settings, view files that do not have access, and so on. For example, if you create standard user accounts on your computer and reserve administrator permissions for your user account, you must enter the account password when a standard user wants to install software, change system settings, or do anything else that is prohibited. Each user account has its own folder in the C:\Users folder. Personal files from your user account, such as Documents, Downloads, and Desktop folders, are stored here. Most apps store their data and settings in a user-specific application data folder, so each user can have their own program settings and data. Keep in mind that some poorly designed applications (especially older games) can store their backup files in one place for all users of the system, as this was how many Windows applications worked in the past. Guest accounts are guest accounts a special user account that is temporarily intended for people who use the computer. If you have a guest who wants to use your computer to browse the Internet or check emails, you can give them access to the guest account instead of allowing them to use your current account or creating a new account for them. This ensures that you do not snoop over your personal information, even by accident. A extremely personal stuff, and if someone gives you access through a guest account, you will rest instead of looking over your shoulder and worrying about accidentally opening your emails or seeing an incoming private message. Guest accounts also have limited access, so users cannot install software or change system settings. Being able to multiple user accounts at the same time, you don't even need to log off to use your computer. Just lock the screen and allow the guest to log into the guest account. Programs will still run in the background, and you can log off from the guest account and unlock the main user account desktop session when you're done. By default, the Guest account is disabled in Windows 7 and 8. To use the Guest account, you must enable it in the User Accounts screen in control panel. To do this, select User Accounts in Control Panel, click Change Account Type, and then click Guest Account. To enable it, click Power On. It will appear on the lock screen like any other account. NOTE: The Guest account is not available in Windows 10. However, you can create a new account that mimics the Guest account and gives guest users limited access. RELATED: How to let someone else use your computer without having to give them access to all the stuff interesting is that Windows support for multiple user accounts works so well now when so many people own personal laptops. In Windows 98, when several people shared desktop computers in the same household, it would have been more useful to support multiple user accounts. Useful.
