For the diminutive name Dennis, see Dennis. D-D fomm and cursive versions, give letters in lowercase and uppercase. Latin Alphabet Writing System Alternative Representations NATO Phonetic Alphabet Delta Code Morse -- International Maritime Navigation Code Optical Telegraph Braille American Manual Alphabet D (Give, Plural Des or DD) is the fourth letter of the original Latin alphabet. History is its origin in the hieratic writings of the letter de Egypt, its oldest ancestor received the name Deret (hand), when the Phoenician adopted it, called it Daleth (door). Greeks, when employing the Phoenician letter it named delta (Δ, δ) and the shape of a triangle. Etruscans and Romans were also delta employed and today we know that D was responsible for the design. Phonetics and D code is a sound linguistic consonant. Letter D with the meaning of diacritics ĐđĐđĐđĐđĐđĐđĐđĐđĐđĐđĐđĐđĐđĐđĐđĐđđ de de Phoenician dallet was meant by the door and represented by the simplified Egyptian hieroglyph of a door. It gave birth to the Delta of the Greeks and our D represents the musical note D in certain languages (e.g. English and German) in d Roman numeral d is worth 500 is used as the abbreviation of Dom or Donna. This The eits d and D. portals of linguistics obtained from insert\_drive\_fileDocumentosLimite of 5,000 characters. Use the arrows to translate more. Typical Christmas flowers, parrot bills are very well represented in this arrangement full of glitter and vibrant colors. Vase-filling balls combine charm and modernity. Vitamin D, also known as hydroxyvitamin D or 25 (OH) D, aims to verify the concentration of vitamin D in the blood, as it is an essential vitamin for regulating phosphorus and calcium levels in the blood, for example a fundamental role in bone metabolism. This test is usually requested by the doctor to monitor vitamin D replacement therapy or when there are signs and symptoms related to bone crime, such as muscle pain and weakness, for example, often requested with a dose of calcium, PTH and phosphorus in the blood. Vitamin D is mainly used to diagnose vitamin D deficiency, in addition to hypervitaminosis D. However, the doctor may also request this examination if there are signs and symptoms of bone dedification, as vitamin D is one of the factors responsible for regulating calcium and phosphorus concentration besides promoting mineralization of bones. This test is also requested to monitor vitamin D replacement therapy and assist in the inter-diagnosis of rickets, osteoporosis and osteomalacia, a disease characterized by delicate and brittle bones in adults. In addition to vitamin D supplements, an evaluation of calcium, parathyroid hormone and phosphorus levels in the blood can be requested, as phosphorus is also related to the bone formation process. Understand how blood phosphorus tests are done. In addition to being indicated to examine hypo and hypervitaminosis and bone changes, Vitamin D testing is indicated for people who are considered to be a risk group, who are above 60 years of age, who are exposed to the sun or who are not in contact with the sun, pregnant women and women in the regular breastfeeding phase, people with endocrine changes, people with kidney disease or malabsorption syndrome, or who use drugs that can interfere with the process of formation and erosion of this vitamin. This signal exists because this group of people have a high risk of developing complications related to changes in this vitamin level, and it is important that they are regularly monitored and treated according to medical recommendation, which is often done through vitamin D supplementation. The examination is carried out, a small amount of blood is being removed, which is sent to the laboratory for analysis, it is not necessary to perform any preparations. Vitamin D arises from a substance derived from cholesterol present in the skin, that when stimulated by ultraviolet light from the sun, it is converted into cholecalciferol, known as vitamin D. Vitamin D produced is metabolized in the liver, which turns into 25-hydroxyvitamin D, which, under the influence of parathyroid hormone, is converted into 1,25-dehydroxyvitamin D, which corresponds to the active and stable form of vitamin D and is responsible for increasing calcium absorption in the intestine and consequently increasing the concentration of calcium in the blood. Doses are given to both forms of vitamin D, with 25-hydroxyvitamin D supplements being higher to identify vitamin D deficiency, while 1.25-dehydroxyvitamin D is usually requested for people with heart disease. What results are possible from the results of 25-hydroxyvitamin D supplements to indicate whether the person has a sufficient amount of vitamin D circulating in the blood for the maintenance of bone health. According to the 2017 recommendation of the Brazilian Society of Clinical Pathology/Laboratory Medicine and the Brazilian Society of Endocrinology and Metabiology[1], vitamin D levels are: &gt; 20 ng/ml; For those belonging to the risk group: 30 and 60 ng/mL.In addition, it is determined that there is a risk of poisoning and hypercalcemia when vitamin D levels are above 100 ng/ml. Regarding levels considered to be inadequate or deficient, studies are being carried out with this objective, although it is recommended that those who present the recommended values are monitored by the doctor and, according to the identified level, the most appropriate treatment is undertaken. Low values of vitamin D indicate hypovitaminosis, which may be due to exposure to poor sun or poor intake of foods rich in vitamin D or its precursors such as egg, fish, cheese and mushrooms, for example. Vitamin D.In also meet other foods rich in addition, diseases such as liver statoris, cirrhosis, pancreatic insufficiency, inflammatory diseases, rickets and osteomlacia and diseases with inflammation in the intestine can cause vitamin D insufficiency or deficiency. Prolonged exposure to the sun does not lead to hypervitaminosis, as the body is able to The amount of vitamin D and when optimal concentrations are identified, it is indicated that vitamin D synthesis is inhibited by sun stimulation and therefore, there is no toxic level of vitamin D due to prolonged exposure to the sun. Sunbathe.
