## Android sign apk command line

<sup>1</sup> The file is already signed with the debug key and aligned with the zipalign, so you can install it on one device immediately. Or to create an APK and immediately install it on a running emulator or connected device, invoke `installdebug` instead: `gradle installDebug` instead: `gradle installDebug` installed the debug part in the above task. Apk should be made. The easiest way to create an app bundle is by using Android Studio. However, if you need to create an app bundle from the command line, you can do so using the gradle or bundletool described in the sections below. `are`. Navigate to `com.android.tools.build` &gt; `aapt2`. Copy the name of the latest version of AAPT2. Enter version name should go. `Root/...`, `property/...`, and `lib/...` `lib/...` You can leave which file type is unpressed: Includes signing on. For more information, see `apksigner` reference. Note: To use the `apksigner` tool, you must have an modification of Android SDK build tools 24.0.3 or higher. You can update this package using SDK Manager. Verify that your APK has been signed: `apksigner verify my-app-release.apk` open the configured gradle module-level to sign your app. File and add signing configurations with entries for `StoreFile`, `StorePassword`, `KeyAlias`, and `KeyPassword`, and

then pass that object to the signing config property in your build type. For example: Android { ... Defaults (...) signings { Release { // You must either specify an absolute path or include the // keystore file in the same directory as the build.gradle file. Store file file (my release-key.jks) storepassword password keyAlias my aka keypassword password } Note: In this case, keystore and key passwords are directly visible in the build.gradle file. For better security, you should remove signature information from your build file. Now, when you create your app by applying a gradle task, Gradle signs your app (and runs zipline) for you. Additionally, because you have configured the release build with your signing key, the install job is available for that build type. So you can build, align, sign and install release APK on an emulator or device with installrelease function. An app signed with your private key is ready for delivery, but you should first read more about publishing your app and reviewing the Google Play Launch checklist. Checklist.
