Baby cradle planets

Its findings were presented Tuesday at the Extreme Solar System III conference in Waikoloa Beach, Hawaii. The image of HD 100546 obtained with GPI in near infrared wavelengths. The Hayne Curry/Gemini Observatory discovered about seven years after HD 8799 was made and its planets became the first multi-planet system ever image and discovery. Hd 100546 looks a lot like HD 8799, hopefully providing that scientists can use the new star system to explore the evolution and evolution of a multi-planet system like our own solar system. There is also another major impact of the findings. Current exoplanet research often relies on space telescopes such as Hubble or Kepler to actually discover and characterize various exoplanets. Because they are far from the earth's surface, they have a better wide area to see. Many like Hubble also have devices for collecting optical data — and not just infrared like GPI. Through this study, though, Curry can work the case that makes ground-based equipment, if it is properly developed and implemented, just as well. Tools like GPI are starting to bridge the gap between what's appearing and what's really out there. It could be more cost-effective just to increase observatory equipment here on the surface instead of planning to launch separate probes and telescopes into interstellar space. Lisa Kaltenagar, an astronomer and exoplanet researcher at Cornell University associated with the study, agrees with that sentiment. I love the optimism of what we can do on the ground, she says. As the ultimate goal of exoplanet research is to find another world like Earth that is capable of sustaining life, the best place to conduct that research can actually be the only one here on Earth. Myself.
