In meiosis, diathren cells pass through a reduced dividing process in which the number of chromoths in a cell is divided into half. The main result of meiosis is 4 haploid cells, which are genetcly different and from parent (biploid) cells. Each superinfnimating cell contains half the number of chromo bodies in a diamphibular cell. 4 answ 2a. 2 answ 2b. 2 answ 3a. see explanation 1 answ 3b. 2 answ 4a. 2 answ 4b. According to studies conducted by Alfred Sturtevant, by finding the frequency of re-combining for a pair of genes, we can determine the relative distance between genes. If two genes on the same chromotype are close together, the re-combination is low; therefore, crossovers will rarely occur. On the other hand, the frequency of re-combining is high if the genes are far apart. In this case, the two genes are usually independently classified as those that are distant from each other. 3 menstruates 5. See explanation 2 answ 321 Page 332
